6. Conclusion

1. Introduction

The Calculator Mini Project aims to develop a simple calculator application in Python to perform basic arithmetic operations.

2. Problem Statement

The topic can be any topic to solve a daily life problem or a game in Python

Design and implement a calculator application that can add, subtract, multiply, and divide numbers entered by the user.

3. Objective

The objective of this project is to create a user-friendly calculator that provides accurate results for arithmetic operations.

4. Methodology

- Use Python programming language for development.
- Implement a user interface using basic input/output functions.

- Utilize functions for each arithmetic operation (addition, subtraction, multiplication, division).
- Handle user input validation to ensure the calculator operates correctly.

5. Implementation and Screenshots

The screenshot shows the JupyterLab interface with a code editor containing the following Python code:

```
[ ]: #Our Calculator
first=input("Enter first number:")
second=input("Enter second number:")
first=int(first)
second=int(second)
print("--Press keys for operator(+,-,*,/,%)--")
operator=input("Enter operator:")
if operator=="+":
    print(first+second)
elif operator=="-":
    print(first-second)
elif operator=="*":
    print(first*second)
elif operator=="/":
    print(first/second)
elif operator=="%":
    print(first%second)
else:
    print("Invalid Operation")
```

The screenshot shows the JupyterLab interface with the same code as the previous screenshot. Below the code editor, the terminal output is visible:

```
[*]: #Our Calculator
first=input("Enter first number:")
second=input("Enter second number:")
first=int(first)
second=int(second)
print("--Press keys for operator(+,-,*,/,%)--")
operator=input("Enter operator:")
if operator=="+":
    print(first+second)
elif operator=="-":
    print(first-second)
elif operator=="*":
    print(first*second)
elif operator=="/":
    print(first/second)
elif operator=="%":
    print(first%second)
else:
    print("Invalid Operation")

Enter first number: 12 For history. Search history with c-/c-1
[ ]:
```

```
[1]: #Our Calculator
first=input("Enter first number:")
second=input("Enter second number:")
first=int(first)
second=int(second)
print("--Press keys for operator(+,-,*,/,%)--")
operator=input("Enter operator:")
if operator=="+":
    print(first+second)
elif operator=="-":
    print(first-second)
elif operator=="*":
    print(first*second)
elif operator=="/":
    print(first/second)
elif operator=="%":
    print(first%second)
else:
    print("Invalid Operation")

Enter first number: 100
Enter second number: 10
--Press keys for operator(+,-,*,/,%)--
Enter operator: /
10.0

[ ]:
```

6. Conclusion

Overall, the Calculator mini project demonstrates the fundamental concepts of programming in Python and serves as a practical exercise for implementing basic functionality in a real-world application Successfully.
